

// A WORKING SESSION

AgentFactory

You've seen AgentFactory and you're interested in collaboration. Today isn't only a product pitch — it's a working session on whether we should harden it for enterprise use in your environment, together.

The problem

Live demo

What's different

Current maturity

How we'd collaborate

// WHY THIS MATTERS

Getting an agent to write code is **the easy part**

The backlog grows — the team doesn't. Agent pilots impress in a demo but rarely reach production. The hard part isn't generating code. It's letting an agent touch real backlog, real repositories and a real delivery flow — safely, with clear ownership and review gates.

No quality gates, no audit, no clear ownership — that's where pilots stall. That's the gap this is built to close.

// LIVE · THE BOARD IS THE CONTROL PLANE

This is real. **Let's put one task through it.**

The live board — real stations, your work moving left to right.

Take one task down the line and watch a worker pick it up.

A different agent reviews the work than the one that built it.

The delivery station follows your deploy pipeline and updates the task in your source system when that integration is configured.

• **LIVE DEMO**

"If it's not on the board, it didn't happen." The board is the control plane — not just a UI.

The first reporting layer is the board itself — the same lifecycle that controls the work.

// STATIONS, NOT A BLACK BOX

Process is built in — not promised afterward

HOW AI IS USUALLY SOLD

- › Task → Solved
- › One black box in the middle
- › Quality = hope

HOW AGENTFACTORY RUNS

- › **Understand** → **Spec** → **Build** → **Review** → **Deliver**
- › Each station: a fixed instruction + a quality gate

An isolated git worktree per task; a reviewable diff against the merge-base

- › A different agent reviews; a human checkpoint before delivery

Quality lives in the stations, gates and review loop — not only in the model.

// THE CONTROL MODEL

Agents **cannot approve their own work**

// WHERE IT IS TODAY — HONESTLY

A strong control model — not yet an enterprise platform

STRONG TODAY

- › Local-first; simple single-file datastore for the current prototype
- › MCP interface; one isolated git worktree per task
- › Reviewer loop; enforced human review gate
- › Azure DevOps / GitHub delivery bridge

NOT YET

- › Single-user / operator-controlled — no SSO or RBAC
- › No exportable audit log or retention policy
- › No enterprise database / deployment profile yet
- › Basic observability; no policy-by-risk

Everything shown today runs now; the enterprise hardening is exactly what we propose to scope together.

// WHAT WE'D HARDEN TOGETHER

The enterprise-readiness backlog

Area	Current strength	Enterprise hardening needed
Identity	Local / operator-controlled	SSO/OIDC, RBAC, approval roles
Audit	Board history + task activity	Exportable audit log, retention policy
Security	Worktree isolation, no direct agent-to-task-source coupling	Secrets vault, least-privilege tokens, threat model
Deployment	Local-first	Docker / Kubernetes, backup, upgrade path
Governance	Human review gate	Policy by task type, repo, risk level
Model control	Human-supervised use	Approved model list, data-boundary policy, prompt/tool policy
Observability	Board + token metrics	Enterprise logging, alerts, dashboards
Compliance	Human-supervised workflow	DPA, data-flow docs, model/data policy

We're showing you the gaps on purpose. That honesty is the basis for a partnership — and the backlog for the pilot.

// PORTABILITY · NO LOCK-IN

You own the process — even if we operate it

ALP — THE OPEN PROTOCOL

- › Stations, lines and gates as an open protocol

Your station definitions in plain text — you own them

- › Audit history in git — portable
- › No lock-in, no migration; take your process with you

AGENTFACTORY — THE IMPLEMENTATION

- › The running system, built on ALP
- › What you saw in the demo
- › Operated by us — or, after hardening, by you

Like git and GitHub: the protocol is portable; the operated service is optional.

// HOW WE'D COLLABORATE · SAME AGENTFACTORY FOUNDATION

Two ways to collaborate — same foundation

TRACK A · ENTERPRISE CO-BUILD PILOT

Best if you want AgentFactory hardened for your environment.

- › Six-month, fixed-scope pilot
- › One real backlog slice — or a greenfield product area
- › Harden together: SSO/RBAC, deployment, audit, security model, operating procedures
- › You own the requirements, process definitions and operational learning
- › At the end: continue together, operate it yourselves, or stop — no lock-in

TRACK B · OPERATED FACTORY LINE (OPTIONAL)

Best if you want throughput while the platform matures.

- › We set up and operate a line for selected tasks
- › You keep the approval gates and source-system ownership
- › We provide line management, monitoring and rework handling
- › Can run alongside the co-build pilot as a practical proof point

The question for today: which collaboration model is the safest first step for you?

// NEXT STEP

What we'd need to **start**

One backlog source

A real queue we can connect to — Jira, Azure DevOps or a backlog slice.

Three low-risk candidate tasks

Concrete first tasks to run the line end to end.

One technical / security contact

To scope the hardening backlog against your controls.

One business sponsor

To own success criteria and the decision at six months.

Agree the pilot shape

Greenfield or backlog slice; scope and gates, with success measures: cycle time, clean pass rate, rework rate, human-override rate.

A shared decision point

At six months: continue, take it over, or stop — no lock-in.

A first controlled line can run quickly; enterprise hardening is the six-month collaboration.

// ARCHITECTURE

How it's built

ONE DB OWNER

Six packages, npm workspaces, strict TypeScript. A single package owns the datastore and every lifecycle rule — the state machine lives in one place.

THREE SUPERVISORS

Dispatcher spawns one fresh agent session per queued task. Reviewer posts an advisory second-agent verdict. Watcher verifies delivery on the git host over REST — no LLM.

LOCAL & ISOLATED

Task state is a local datastore; each task runs in its own git worktree. Nothing about the work has to leave your network.

For deep IT or compliance questions, we propose a separate technical review of the ALP spec and control model with your security team.

// THE OPERATED LINE, IN DETAIL

Capacity you can dial — under your gates

A **line-manager** watches the board, catches stuck tasks and handles rework, with a team behind them.

- › Capacity is one dial: add a line for more parallel throughput; pause and keep the backlog and definitions.
- › You keep the approval gates and own the source system throughout.

HOW WE'D MEASURE IT

Agent work can continue asynchronously;
approvals stay in your working hours and under your control.

We track **clean pass rate, rework rate and human-override rate** straight from the board — no separate report.

// THE TRANSITION · L1 → L5

You move up the levels by **tightening or loosening a gate**

Autonomy is a property of the deployment, not the model. A pilot starts at L3 — review everything — and earns its way toward L4/L5 as trust builds. Aligned to the Context& AI Transition model.

// MARKET THESIS · FROM HOURS TO FACTORIES

Why the delivery model is changing

When AI accelerates the work itself, every task shrinks — and a business that sells hours × people shrinks with it. When delivery is no longer measured in time, the question changes: not how many hours, but what got delivered.

THE SHIFT

From estimate, staff, invoice time

To fixed price on bounded deliveries

To a subscription on running capacity

› Scale up and down like cloud — not like hiring

Context for our commercial model — not the reason for today's meeting. Today is about co-building an enterprise-ready platform.

// OPERATED-LINE PRICING · ILLUSTRATIVE

The operated line — indicative pricing

Capacity	List price (anchor)	What you get
1 line	from 40,000 kr/mo	Board, operation and a line-manager — plus architect / workshop / discovery hours
More lines	same anchor per line	Parallel capacity on the same board
Pause	small standby fee	Backlog, context and definitions preserved — restart is one click

ILLUSTRATIVE · CLASSIC TEAM

≈ 3.0M kr

2,000 hours · classic hourly rate — customer carries estimate risk

÷ 2

ILLUSTRATIVE · ON LINES

≈ 1.5M kr

Same calendar time · lines + architect hours

Round anchors, not a quote — and part of the operated track, not the co-build pilot. Method: classic estimate → halve → compose lines + add-ons.
